```
def ttt(G):
    seen = []
    for v in G: seen[v] = False
    a,b,t = 0,[0],0
    for v in G:
        a+= 1
        if not seen[v]:
            t += 1
            ddd(G,v,seen,b)
    print a,b,t
```

```
def ddd(G,v,seen,b):
    print v,
    seen[v] = True
    for nbr in G[v]:
        b[0] += 1
        if not seen[nbr]:
            ddd(G,nbr,seen,b)
    print v,
```

```
G = {'A': [],
      'B': ['C', 'D', 'F'],
      'C': ['B', 'F'],
      'D': ['B', 'F'],
      'E': ['G'],
      'F': ['B', 'C', 'D'],
      'G': ['E']}
```

- Draw  $G$ :

- Show the output from `ttt(G)`.

2. [4 marks] For integers  $1 < j < n$ , Euclid's  $\text{gcd}(n,j)$  performs  $O(\underline{\hspace{2cm}})$  integer divisions, each on numbers with  $O(\underline{\hspace{2cm}})$  bits. One such division takes  $O(\underline{\hspace{2cm}})$  time, so the total runtime is  $O(\underline{\hspace{2cm}})$ .

3. [4 marks] Use binary numbers and Aryabhata's algorithm. Complete the work below: find the integer square root of  $0b1011011101$ . **Circle** the square root. **Draw a box** around the remainder.

$$\begin{array}{r} 1 \quad 1 \\ \hline \sqrt{10 \quad 11 \quad 01 \quad 11 \quad 01} \\ 1 \qquad \qquad \qquad 1 \\ \hline \qquad \qquad \qquad 1 \quad 11 \\ 101 \qquad \qquad \qquad 1 \quad 01 \\ \hline \end{array}$$

```
def rmult(x,y):  
    if y==0:  
        print '(',x,y,')',0  
        return 0  
    elif 0==y%2: # y is even  
        t = 2*rmult(x,y/2)  
        print '(',x,y,')',t  
        return t  
    else: # y is odd  
        t = x+2*rmult(x,y/2)  
        print '(',x,y,')',t  
        return t
```

- Show the output from `rmult(25,25)`.

5. [3 marks] Consider the MillerRabin test to see whether 561 is prime. A number  $a$  is picked randomly from this set of integers: \_\_\_\_\_ . Next,  $a$  is raised to these powers  $(\text{mod } \underline{\hspace{2cm}})$ :

\_\_\_\_\_. Assume that  $a^{560} = 1 \pmod{\underline{\hspace{2cm}}}$ . Then, by the \_\_\_\_\_ test, 561 is composite if \_\_\_\_\_.

6. [3 marks] In each case, give the simplest  $\Theta$  expression for  $T(n)$ . Hint: master theorem: compare  $a$  and  $b^d$ .

- $T(n) = 9T(n/3) + \Theta(n^2)$   
a: \_\_\_\_\_ b: \_\_\_\_\_ d: \_\_\_\_\_  $T(n) \in \Theta(\underline{\hspace{2cm}})$
- $T(n) = 6T(n/2) + \Theta(n^2)$   
a: \_\_\_\_\_ b: \_\_\_\_\_ d: \_\_\_\_\_  $T(n) \in \Theta(\underline{\hspace{2cm}})$
- $T(n) = \Theta(n^3) + 8T(n/4)$   
a: \_\_\_\_\_ b: \_\_\_\_\_ d: \_\_\_\_\_  $T(n) \in \Theta(\underline{\hspace{2cm}})$

7. [3 marks] Compute  $5^{24} \pmod{7}$ . Show your work.

- Let  $t = 9801$ . Assume that, for all integers  $y$  with  $0 \leq y \leq t$ , `rmult(x,y)` returns  $x$  times  $y$ . Complete the proof below.

**Claim.** `rmult(x,9802)` returns  $x$  times 9802.

**Proof.** 9802 is even, so `rmult(x,9802)` returns \_\_\_\_\_ . Also,

\_\_\_\_\_ is less than \_\_\_\_\_,

so by our assumption \_\_\_\_\_ returns \_\_\_\_\_.

So \_\_\_\_\_
