

## Lecture 27: Wednesday March 19, 2003

### today

- biconnected components
- muddytown

### announcements

**recall: bicomponent (= biconnected component)**

- *cut vertex* removal increases number of components
- *biconnected graph* connected and no cut vertex
- *bicomponent* maximal biconnected subgraph
- *v* cut vertex iff, w.r.t. dfs tree

root: more than one subtree

not root: child subtree has no back edge to proper *v*-ancestor

## recall: finding bicomponents via depth first search

- algorithm: for each  $v$ , for each child  $w$ , keep track of furthest back edge from  $w$ -subtree
- how to implement algorithm using dfs?
  - 1st encounter of child  $w$  of parent  $v$ 
    - \* recurse from  $w$
  - last encounter of  $w$ , just before backing up to  $v$ 
    - \* check whether  $v$  cuts off  $w$ -subtree
  - maintain **dfn**, **back**, **parent** for each  $v$ 
    - \* **parent**: parent in DFS tree
    - \* **dfn**: number, by discovery, in DFS
    - \* **back**: dfn of furthest ancestor (of descendant)
    - \* update **back** when backedge 1st encountered
    - \* update **back** when backing up
  - maintain edge stack
    - \* push edge when edge 1st encountered
    - \* pop edges when cutpoint discovered

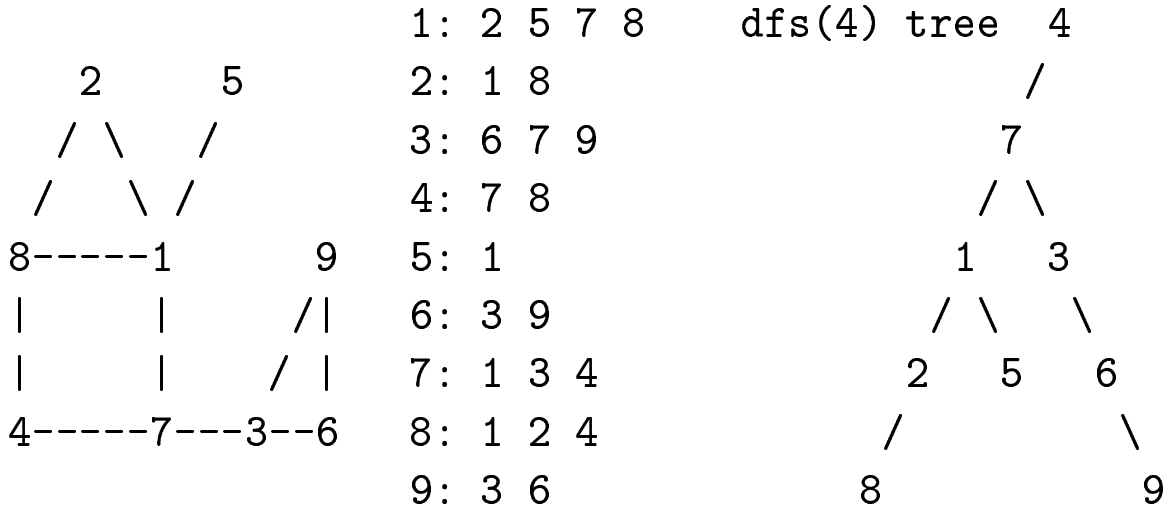

```

bicomponents()      (*version 2001, based on CLRS DFS*)
  empty stack; dfnum <- 0
  for all v do
    parent[v] <- 0; dfn[v] <- 0; back[v] <- n+1
  for all v do
    if dfn[v]=0 then bidfs(v)
end_bicomponents

bidfs(v)
  inc(dfnum); dfn[v] <- dfnum; back[v] <- dfn
  for each neighbour w do
    if dfn[w]=0 then                                     (*1st w encounter*)
      push [vw]; parent[w] <- v                          (*tree edge*)
      bidfs(w)
      (* backup up from w to v*)
      if back[w] >= dfn[v] then (*v root or cuts off w? yes*)
        print 'new bicomponent'
        repeat: pop and print edge
        until popped edge is [vw]
      else                                               (*v root or cuts off w? no*)
        back[v] <- min {back[v],back[w]}
      (*end backup from w to v*)
    elsif dfn[w]<dfn[v] and w<>parent[v] then (*back edge*)
      push [vw]; back[v] <- min {dfn[w],back[v]}
end_bidfs

```

- example trace: execute `bidfs(4)` on the graph below, assuming no previous `bidfs()` calls (answer on the next page)

|                          | back | [1  | 2    | 3    | 4    | 5    | 6    | 7    | 8 | 9] |

## bicomponent algorithm: analysis

- correctness?

the truth is out there

- complexity?

– time: constant for each vertex/edge encounter

$$\Theta(c_1n + c_2 \sum_v \text{deg}(v) = c_1n + 2c_2m) = \Theta(n + m)$$

– space: assume adjacency list representation

\* graph, arrays of size  $n$ , edge stack, runtime stack

\* edge stack:  $O(m)$  since each edge pushed

\* runtime stack:  $O(n)$  since at most  
 $n$  constant size activation records

$$* \Theta(n + m) + \Theta(n) + O(m) + O(n) = \Theta(n + m)$$

## muddytown

- problem: dirt streets, muddy when it rains
- goal: to be able to walk without muddying shoes
- idea: pave enough streets to walk anywhere
- problem: given street paving costs, find min cost paving
