

CMPUT325: Applications of λ -calculus

Dr B. Price and Dr. R Greiner

18th October 2004

Introduction

- ▶ λ -calculus models calculation using only 2 rules
- ▶ Can only represent functions and application
- ▶ Explicit datastructures and control structures: absent!
- ▶ How can λ -calculus implement any calculation?
- ▶ Possible to formalize data and control as function application
- ▶ Standard idioms map high-level data structures and control into λ -C expressions

Abstract Numbers I

- ▶ The concept of number can be built up from "0", "successor"

i.e., $1 = \text{successor}(0)$, $2 = \text{successor}(1)$, $3 = \text{successor}(2)$...

- ▶ Let $\sigma(n) \equiv \text{successor}(n)$... so $1 = \sigma(0)$, $3 = \sigma(\sigma(0))$, ...

- ▶ Numbers \approx a sequence of function applications

- ▶ Addition is a short-hand for composing successor

$$2+1 \equiv \sigma(\sigma(\sigma(0))) \equiv 3$$

- ▶ "Zero" is called the additive identity.

- ▶ $\Rightarrow n + 0 = n$ for any n

Abstract Numbers II

- ▶ Successor and addition have natural inverses:

- ▶ Predecessor is the number before the current one.

Let $\pi(n)$ be the predecessor of n .

- ▶ $b = \sigma(a) \Rightarrow \pi(b) = a$

- ▶ Subtraction is the inverse of addition: $a+b=c \Rightarrow c-b=a$

- ▶ Multiplication can be defined in terms of addition;
and division as inverse of multiplication

- ▶ Negative numbers and real-numbers can be derived from
addition and division

- ▶ First, we need to define the successor function and zero

λ -Calculus Numbers

- ▶ Church found idioms with the desired properties:
 - ▶ Each number \approx 2-argument functions
 - ▶ $0 \equiv (\lambda s \mid (\lambda z \mid z)) \equiv (\lambda s z \mid z)$
 - ▶ Successor $\sigma(n) \equiv (\lambda x \mid (\lambda s z \mid s (x s z))) \langle n \rangle$
 - ▶ Always returns 2-arg function $(\lambda s z \mid s (\langle n \rangle s z))$
 - ▶ Note: $(\lambda s z \mid s (\langle n \rangle s z))$ applies $\langle n \rangle$ to 2 function-constants
 - ▶ Application "copies" body of number into new function
- ▶ The successor of zero:

$$\sigma(0) \equiv (\lambda x s z \mid s (x s z)) (\lambda s z \mid z)$$

Free vars get bound in $(\lambda s z \mid z)$? No - no free vars!

$$\rightarrow (\lambda s z \mid s ((\lambda s z \mid z) s z))$$

$$\rightarrow (\lambda s z \mid s ((\lambda s z \mid z)) s z)$$

$$\rightarrow (\lambda s z \mid s z) \equiv (\lambda s z \mid (s z))$$

Successor

- ▶ The successor of one:

$$\sigma(1) \equiv (\lambda x s z \mid s (x s z)) (\lambda s z \mid (s z))$$

$$\equiv (\lambda s z \mid s ((\lambda s z \mid (s z)) s z))$$

$$\equiv (\lambda s z \mid s ((\lambda s z \mid (s z)) s z))$$

$$\equiv (\lambda s z \mid s (s z)) \equiv (s z \mid (s (s z)))$$

- ▶ The successor of two:

$$\sigma(2) \equiv (\lambda x s z \mid s (x s z)) (\lambda s z \mid (s (s z)))$$

$$\equiv (\lambda x s z \mid s ((\lambda s z \mid (s (s z))) s z))$$

$$\equiv (\lambda x s z \mid s ((\lambda s z \mid (s (s z))) s z))$$

$$\equiv (\lambda x s z \mid s (s (s z)))$$

$$\equiv (\lambda x s z \mid (s (s (s z))))$$

Addition

- ▶ $(+ m n) \equiv (\lambda x y \mid (\lambda s z \mid x s (y s z))) \langle m \rangle \langle n \rangle$
 - ▶ Returns a 2-arg function: $(\lambda s z \mid \langle m \rangle s (\langle n \rangle s z))$
 - ▶ $\langle n \rangle$ applied to $s z$ (copies body into new function)
 - ▶ $\langle m \rangle$ is applied to s and copy of $\langle n \rangle$
 - ▶ A total of $\langle m \rangle$ successors are composed onto $\langle n \rangle$

- ▶ Addition of 1+1

$$\begin{aligned} & (\lambda x y \mid (\lambda s z \mid x s (y s z))) \\ & \quad (\lambda s z \mid s z) \quad (\lambda s z \mid s z) \\ \equiv & (\lambda s z \mid (\lambda s z \mid s z) s ((\lambda s z \mid s z) s z)) \\ \equiv & (\lambda s z \mid (\lambda s z \mid s z) s s z) \\ \equiv & (\lambda s z \mid s s z) \end{aligned}$$

Successor as Addition

- ▶ Check: $\sigma(n) = (+ 1 n)$

$$\begin{aligned} & (\lambda x y \mid (\lambda s z \mid x s (y s z))) (\lambda s z \mid s z) \\ \equiv & (\lambda x y \mid (\lambda s z \mid (\lambda s z \mid s z) s (y s z))) \\ \equiv & (\lambda x y \mid (\lambda s z \mid (\lambda s z \mid s z) s (y s z))) \\ \equiv & (\lambda y \mid (\lambda s z \mid s (y s z))) \end{aligned}$$

- ▶ ... equivalent to our definition of successor !
 $(\lambda x s z \mid s (x s z))$

Multiplication

- ▶ $(* m n) \equiv (\lambda x y (\lambda s | x (y s))) \langle m \rangle \langle n \rangle$
 - ▶ $\langle n \rangle$ passed as 1st argument to number $\langle m \rangle = (\lambda s z | \dots)$
 - ▶ Body of $\langle n \rangle$ is copied once for each successor op in $\langle m \rangle$

- ▶ $(* 3 2)$

$$\begin{aligned}
 & (\lambda x y (\lambda s | x (y s))) \\
 & \quad (\lambda s z | s (s (s z))) (\lambda s z | s (s z)) \\
 \equiv & (\lambda s | (\lambda s z | s (s (s z))) ((\lambda s z | s (s z)) s)) \\
 \equiv & (\lambda s | (\lambda s z | s (s (s z))) ((\lambda s z | s (s z)) s)) \\
 \equiv & (\lambda s | (\lambda s z | s (s (s z))) (\lambda z | s (s z))) \\
 \equiv & (\lambda s | (\lambda s z | s (s (s z))) (\lambda z | s (s z))) \\
 \equiv & (\lambda s | (\lambda z | \\
 & \quad (\lambda z | s (s z)) ((\lambda z | s (s z)) ((\lambda z | s (s z)) z))) \\
 \equiv & (\lambda s z | s (s (s (s (s (s z))))))
 \end{aligned}$$

◀ ◻ ▶ ◀ ◻ ▶ ◀ ≡ ▶ ◀ ≡ ▶ ≡ ↺ ↻

Multiplication by Zero

- ▶ $(* 0 m)$

$$\begin{aligned}
 & (\lambda x y | (\lambda s | x (y s))) (\lambda s z | z) \langle m \rangle \\
 \equiv & (\lambda y | (\lambda s | (\lambda s z | z) (y s))) \langle m \rangle \\
 \equiv & (\lambda y | (\lambda s | (\lambda s z | z) (y s))) \langle m \rangle \\
 \equiv & (\lambda y | (\lambda s | (\lambda z | z))) \langle m \rangle \\
 \equiv & (\lambda y | (\lambda s z | z)) \langle m \rangle
 \end{aligned}$$

- ▶ Take any number $m = (\lambda s z | s s \dots s z)$

$$\begin{aligned}
 & (\lambda y (\lambda s z | z)) m \\
 \equiv & (\lambda s z | z)
 \end{aligned}$$

◀ ◻ ▶ ◀ ◻ ▶ ◀ ≡ ▶ ◀ ≡ ▶ ≡ ↺ ↻

Predecessor and Subtraction

- ▶ For $n > 0$, predecessor returns the integer before n , otherwise it returns zero
- ▶ There is no way to take apart a λ -calculus expression easily (Predecessor is not simply removing an 's' from the body of a Church number)

PREDECESSOR \equiv

$$n \ (\lambda a g | (a(\lambda b c | c)) (\langle \text{successor} \rangle (a(\lambda b c | c))))$$

$$(\lambda g | 00) \ (\lambda a b | a)$$

- ▶ Applies a **function** that maps (x,y) to $(y,y+1)$ to the pair $(0,0)$ n times
- ▶ Results in the pair $(n-1,n)$
- ▶ The **left number**, $n-1$ is the predecessor
- ▶ $(- m n) \equiv (\lambda m n | n \langle \text{predecessor} \rangle m)$

Boolean Expressions

- ▶ Define the boolean values
 - ▶ True: $T = (\lambda c d | c)$
 - ▶ Returns its first argument
 - ▶ False: $F \equiv (\lambda c d | d)$
 - ▶ Returns its second argument

- ▶ Boolean functions

$$(\text{not } m) \equiv (\lambda x | x F T)$$

$$\equiv (\lambda x | x (\lambda c d | d) (\lambda c d | c))$$

- ▶ Example $(\text{not } t)$

$$\equiv (\lambda x | x (\lambda c d | d) (\lambda c d | c)) \ (\lambda c d | c)$$

$$\equiv (\lambda c d | c) \ (\lambda c d | d) \ (\lambda c d | c)$$

$$\equiv (\lambda c d | c) \ (\lambda c d | d) \ (\lambda c d | c)$$

$$\equiv (\lambda c d | d) \equiv F$$

Boolean Expressions

- ▶ $(\text{and } m \ n) \equiv (\lambda x \ y \mid x \ y \ F)$
 - ▶ So if x is F , will return 2^{nd} arg F
 - ▶ Otherwise if x is T will return 1^{st} arg y

$(\text{and } T \ F)$
 $\equiv (\lambda x \ y \mid x \ y \ F) \ (\lambda cd \mid c) \ (\lambda cd \mid d)$
 $\equiv ((\lambda cd \mid c) \ (\lambda cd \mid d) \ F)$
 $\equiv ((\lambda cd \mid c) \ (\lambda cd \mid d) \ F)$
 $\equiv (\lambda cd \mid d)$
 $(\text{and } F \ T)$
 $\equiv (\lambda x \ y \mid x \ y \ F) \ (\lambda cd \mid d) \ (\lambda cd \mid c)$
 $\equiv (\lambda cd \mid d) \ (\lambda cd \mid c) \ F$
 $\equiv (\lambda cd \mid d) \ (\lambda cd \mid c) \ F$
 $\equiv F \equiv (\lambda cd \mid d)$

OR, ZEROP and Math Predicates

- ▶ $\text{OR}(\langle F \rangle, \langle G \rangle)$ is true if $\langle F \rangle$ is true or $\langle G \rangle$ is true

$\text{OR}(x) \equiv (\lambda w \ z \mid w \ T \ z)$

- ▶ $\text{ZEROP}(n)$ returns true if $n=0$

$\text{zerop}(n) \equiv (\lambda x \mid x \ F \ \text{not } F)$

- ▶ Relations on integers

$x \geq y \equiv \text{zerop}(x - y)$

$x < y \equiv \text{not } x \geq y$

$x = y \equiv x \geq y \ \text{AND} \ y \geq x$

Conditional

- ▶ If P then M else N $\equiv (\lambda uvw \mid uvw) PMN$
- ▶ P is a function returning true T or false F
- ▶ Recall, T returns first argument, F returns second
- ▶ Example: (IF T M N)

$$\begin{aligned} &\equiv (\lambda uvw \mid uvw) TMN \\ &\equiv (\lambda uvw \mid uvw) TMN \\ &\equiv (\lambda vw \mid Tvw) MN \\ &\equiv (\lambda vw \mid (\lambda cd \mid c) vw) MN \\ &\equiv (\lambda vw \mid v) MN \\ &\equiv M \end{aligned}$$

Lists

- ▶ Cons cell (M . N) represented as 1 arg function $(\lambda z \mid z M N)$
- ▶ Cons operator: $(\text{cons } M N) \equiv (\lambda x y (\lambda z \mid z x y)) M N$
- ▶ First: $(\text{car } m) \equiv (\lambda x \mid x T) m$ where $T \equiv (\lambda cd \mid c)$
- ▶ Rest: $(\text{cdr } m) \equiv (\lambda x \mid x F) m$ where $F \equiv (\lambda cd \mid d)$
- ▶ Example: $(\text{car } (\lambda z \mid z M N))$

$$\begin{aligned} &\equiv (\lambda x \mid x T) (\lambda z \mid z M N) \\ &\equiv (\lambda z \mid z M N) T \\ &\equiv (T M N) \equiv ((\lambda cd \mid c) M N) \equiv M \end{aligned}$$

- ▶ Example: $(\text{cdr } (\lambda z \mid z M N))$

$$\begin{aligned} &\equiv (\lambda x \mid x F) (\lambda z \mid z M N) \\ &\equiv (\lambda z \mid z M N) F \\ &\equiv (F M N) \equiv ((\lambda cd \mid d) M N) \equiv N \end{aligned}$$

Alternative Definition of Numbers I

- ▶ Define numerals as recursive lists
 - ▶ $0 \equiv (\lambda x | x)$
 - ▶ $\sigma(n) \equiv (1+ n) \equiv (\text{cons } F \ n)$ for all $n \geq 0$ where $F \equiv (\lambda cd | d)$
 - ▶ $\pi(n) \equiv (1- n) \equiv (\text{cdr } n) \equiv (\lambda x | x \ F)$
 - ▶ $(\text{zerop } n) \equiv (\text{first } n) \equiv (\lambda x | x \ T)$
- ▶ Examples

$$\begin{aligned}\sigma(n) &\equiv (\text{cons } F \ .) \\ &\equiv (\lambda x \ y \ (\lambda z \ | \ z \ x \ y)) \ F \\ &\equiv (\lambda y \ (\lambda z \ | \ z \ F \ y))\end{aligned}$$

Alternative Definition of Numbers II

$$\begin{aligned}1 &\equiv \sigma(0) \equiv (\text{cons } F \ 0) \\ &\equiv (\lambda y \ | \ (\lambda z \ | \ z \ F \ y)) \ (\lambda x \ | \ x) \\ &\equiv (\lambda z \ | \ z \ F \ (\lambda x \ | \ x)) \\ &\equiv [F \ 0]\end{aligned}$$

$$\begin{aligned}2 &\equiv \sigma(1) \equiv (\text{cons } F \ 1) \equiv (\text{cons } F \ (\text{cons } F \ 0)) \\ &\equiv (\lambda y \ | \ (\lambda z \ | \ z \ F \ y)) \ (\lambda z \ | \ z \ F \ (\lambda x \ | \ x)) \\ &\equiv (\lambda z \ | \ z \ F \ (\lambda z \ | \ z \ F \ (\lambda x \ | \ x))) \\ &\equiv [F \ F \ 0]\end{aligned}$$

$$\begin{aligned}3 &\equiv \sigma(2) \equiv (\text{cons } F \ 2) \equiv (\text{cons } F \ (\text{cons } F \ (\text{cons } F \ 0))) \\ &\equiv (\lambda y \ | \ (\lambda z \ | \ z \ F \ y)) \\ &\quad (\lambda z \ | \ z \ F \ (\lambda z \ | \ z \ F \ (\lambda x \ | \ x))) \\ &\equiv (\lambda z \ | \ z \ F \\ &\quad (\lambda z \ | \ z \ F \ (\lambda z \ | \ z \ F \ (\lambda x \ | \ x)))) \\ &\equiv [F \ F \ F \ 0]\end{aligned}$$

Alternate Definition of Plus

- ▶ Analysis of examples of $(+ m n)$

$(+ [0] [0]) \rightarrow [0]$ Easy

$(+ [0] [F 0]) \rightarrow [F 0]$ Easy

$(+ [F 0] [F 0]) \rightarrow [F F 0]$

$\equiv (+ [0] [F F 0])$ Made easy

$(+ [F F 0] [F 0])$

$\equiv (+ [0] [F F F 0]) \rightarrow [F F F 0]$ Made easy

- ▶ Leads to a recursive definition of plus $(+ m n)$

```
plus  $\equiv (\lambda x y |$   
      (zerop x) ;; T returns first arg!  
      y  
      (plus (pred x) (succ y)) ) m n
```

- ▶ Recursive plus is self-referential

- ▶ Need a technique for recursion

Recursion in λ -Calculus

- ▶ Recursion reuses same code repeatedly. Earlier we saw

```
( $\lambda x | x x$ ) ( $\lambda x | x x$ )  
 $\rightarrow (\lambda x | x x) (\lambda x | x x)$ 
```

- ▶ The expression $(\lambda x | x x)$ is preserved indefinitely!

- ▶ Let R be a function. What does this variation do?

```
( $\lambda x | R (x x)$ ) ( $\lambda x | R (x x)$ )  
 $\rightarrow R ( (\lambda x | R (x x)) (\lambda x | R (x x)) )$ 
```

- ▶ Note:

- ▶ 1 copy of R “peeled” off
- ▶ Self-replicating expression preserved:

```
( $\lambda x | R (x x)$ ) ( $\lambda x | R (x x)$ )
```

Fixed-Point Combinator

- ▶ A fixed point for a function is an argument whose image is itself

x is a fixed-point of f , if $f(x)=x$

- ▶ The square function has 2 fixed points $0^2 = 0$ and $1^2 = 1$
- ▶ A fixed-point combinator finds the fixed point of a function.
- ▶ Let Y be a fixed-point combinator. $Y(\text{square})=1$
 - ▶ Because $\text{square}(1)=1$
 - ▶ By definition: $\text{square}(Y(\text{square}))=Y(\text{square})$
- ▶ In general: a fixed-point combinator is a function Y with the property $F(Y(F)) = Y(F)$ for all functions F

λ -Calculus Fixed-Point Combinator I

- ▶ Define a function: $R \equiv (\lambda f \mid \langle \text{body} \rangle)$
 - ▶ Define a fixed-point combinator
- $$Y \equiv (\lambda y \mid (\lambda x \mid y (x x)) (\lambda x \mid y (x x)))$$
- ▶ Apply fixed-point combinator to R to find a fixed-point

$$(Y R) \equiv (\lambda y \mid (\lambda x \mid y (x x)) (\lambda x \mid y (x x))) \quad R$$
$$\xrightarrow{\beta} (\lambda x \mid R (x x)) (\lambda x \mid R (x x))$$

- ▶ Denote fixed-point: $\langle YR \rangle \equiv (\lambda x \mid R (x x)) (\lambda x \mid R (x x))$

λ -Calculus Fixed-Point Combinator II

- ▶ Evaluating $\langle YR \rangle$

$$\begin{aligned} \langle YR \rangle &\equiv (\lambda x \mid R (x x)) (\lambda x \mid R (x x)) \\ &\xrightarrow{\beta} R \left(\underbrace{(\lambda x \mid R (x x))}_{\text{function}} \underbrace{(\lambda x \mid R (x x))}_{\text{self-replicating form}} \right) \\ &\equiv R \langle YR \rangle \end{aligned}$$

- ▶ Evaluate $\langle YR \rangle$ whenever we need a copy of R
- ▶ $\langle YR \rangle$ is an R factory

Specific Fixed-Point Combinators

- ▶ Combinator we use was discovered by Haskell B. Curry

$$Y \equiv (\lambda y \mid (\lambda x \mid y (x x)) (\lambda x \mid y (x x)))$$

- ▶ Combinator discovered by Alan Turing

$$\Theta = (\lambda x \mid (\lambda y \mid (y (x x y)))) (\lambda x \mid (\lambda y \mid (y (x x y))))$$

- ▶ This one works for applicative order reduction

$$\Theta_V = (\lambda h \mid (\lambda x \mid (h (\lambda y \mid (y (x x y)))))) (\lambda x \mid (h (\lambda y \mid (y (x x y))))))$$

Recursion with Haskell Combinator

- ▶ Define: $R \equiv (\lambda f y \mid \langle \text{body} \rangle)$
- ▶ **Normal order** eval of combined R to argument m
 $\langle YR \rangle m$; ; what happen's when we eval $\langle YR \rangle?$
 $\equiv R \langle YR \rangle m$
- ▶ What's next step in Normal order reduction?
- ▶ Do leftmost apply: Apply R to its arguments
 - ▶ R's 1st arg **f** : self-replicating combined function $\langle YR \rangle$
 - ▶ R's 2nd arg **y** : m
 - ▶ R "performs calculations on" its argument **y=m**
 - ▶ R evaluates to either:
 - ▶ a single value, say **n**, for a base case
 - ▶ "copy" of itself stored in **f** applied to a reduced value, $\langle YR \rangle m'$ for recursive case

◀ ◻ ▶ ◀ ◻ ▶ ◀ ≡ ▶ ◀ ≡ ▶ ≡ ◀ ◻ ◻

Recursion Example: Non-recursive

- ▶ Ignoring **f** arg, what does this "sort-of" compute?

$$F = (\lambda f n \mid (\text{zerop } n) \quad ; ; \text{ T returns 1}^{\text{st}} \text{ arg} \\ 1 \\ (* n (f (1- n)))))$$

- ▶ Basically, factorial: $f(0)=1, f(1)=1, f(2)=2, f(3)=6 \dots$
- ▶ Let d be a dummy function constant:

$$F d 0 \rightarrow 1 \\ \text{For } m > 0 \quad F d m \\ \rightarrow (* n (d (1- n)))$$

- ▶ d undefined!

◀ ◻ ▶ ◀ ◻ ▶ ◀ ≡ ▶ ◀ ≡ ▶ ≡ ◀ ◻ ◻

Factorial Example: Base Case

$$F \equiv (\lambda f n | (\text{zerop } n) \quad ;; \text{ T returns first arg} \\ 1 \\ (* n (f (1- n))))$$

- ▶ Use Haskell combinator Y to make F recursive

$$(Y F) \\ \equiv (((\lambda y | (\lambda x | y (x x)) (\lambda x | y (x x))) \\ (\lambda f n | (\text{zerop } n) 1 (* n (f (1- n))))))) \\ \xrightarrow{\beta} \langle YF \rangle \quad ;; \text{ long expr with 2 copies of F}$$

- ▶ Factorial example: base case

$$\langle YF \rangle 0 \quad ;; \text{ what happens when } \langle YF \rangle \text{ is eval'd?} \\ \xrightarrow{\beta} F \langle YF \rangle 0 \\ \xrightarrow{\beta} 1$$

Factorial Example: Recursive Case

$$F \equiv (\lambda f n | (\text{zerop } n) \quad ;; \text{ T returns first arg} \\ 1 \\ (* n (f (1- n))))$$

- ▶ Factorial example: recursive case
(Roughly in partly applicative order...)

$$\langle YF \rangle 1 \\ \xrightarrow{\beta} F \langle YF \rangle 1 \\ \xrightarrow{\beta} (* 1 (\langle YF \rangle (1- 1))) \\ \xrightarrow{\beta} (* 1 (F \langle YF \rangle (1- 1))) \\ \xrightarrow{\beta} (* 1 1) \\ \xrightarrow{\beta} 1$$

Plus Example: Recursive Solution

$(+ [F F 0] [F 0])$
 $\equiv (+ [0] [F F F 0]) \rightarrow [F F F 0]$

$P \equiv (\lambda p x y |$
 $(zerop x)$
 y
 $(p (pred x) (succ y)))$

$(Y P) \xrightarrow{\beta} \langle YP \rangle$
 $\langle YP \rangle 1 2$
 $\xrightarrow{\beta} P \langle YP \rangle 1 2$
 $\xrightarrow{\beta} \langle YP \rangle 0 3$
 $\xrightarrow{\beta} P \langle YP \rangle 0 3 \xrightarrow{\beta} 3$

Summation Example: Recursive Solution

Key idiom: $\text{sum}(n) = n + \text{sum}(n-1)$

$S \equiv (\lambda s n | (zerop n) 0 (+ n (s (1- n))))$

$(Y S) \xrightarrow{\beta} \langle YS \rangle$

$\langle YS \rangle 1$
 $\xrightarrow{\beta} S \langle YS \rangle 1$
 $\xrightarrow{\beta} (+ 1 (\langle YS \rangle (1- 1)))$
 $\xrightarrow{\beta} (+ 1 (S \langle YS \rangle 0))$
 $\xrightarrow{\beta} (+ 1 0) \xrightarrow{\beta} 1$
