

# Approximation algorithm for minimum $\lambda$ -edge-connected $k$ -subgraph with metric costs

MohammadAli Safari and Mohammad R. Salavatipour

Dept. of Computing Science  
University of Alberta

August, 2008

$(k, \lambda)$ -subgraph problem:

- **Input:** Given a weighted undirected graph  $G$  and integer parameters  $k$  and  $\lambda$
- **Output:** Find a minimum weight  $\lambda$ -edge-connected subgraph of  $G$  containing at least  $k$  nodes.

$(k, \lambda)$ -subgraph problem:

- **Input:** Given a weighted undirected graph  $G$  and integer parameters  $k$  and  $\lambda$
- **Output:** Find a minimum weight  $\lambda$ -edge-connected subgraph of  $G$  containing at least  $k$  nodes.

Generalizes many classical problems:

- **k-MST**  $\equiv (k, 1)$ -subgraph problem.  
Approximation factor:  $\sqrt{k}$  [13],  $O(\log^2 k)$  [1],  $O(\log n)$  [12], constant [3, 8] and 2 [9].
- **min-cost  $\lambda$ -edge-connected spanning graph**  
 $\equiv (|V(G)|, \lambda)$ -subgraph problem

$(k, \lambda)$ -subgraph problem in general graphs:

- Introduced recently by Lau et al. [11].
- They obtain an  $O(\log^2 n)$ -approximation for  $(k, 2)$ -subgraph problem.

$(k, \lambda)$ -subgraph problem in general graphs:

- Introduced recently by Lau et al. [11].
- They obtain an  $O(\log^2 n)$ -approximation for  $(k, 2)$ -subgraph problem.
- For arbitrary  $\lambda$ : as hard as the  $k$ -densest subgraph problem [11]; best known approximation factor is  $O(n^{\frac{1}{3}-\epsilon})$  for some  $\epsilon > 0$ .

$(k, \lambda)$ -subgraph problem in general graphs:

- Introduced recently by Lau et al. [11].
- They obtain an  $O(\log^2 n)$ -approximation for  $(k, 2)$ -subgraph problem.
- For arbitrary  $\lambda$ : as hard as the  $k$ -densest subgraph problem [11]; best known approximation factor is  $O(n^{\frac{1}{3}-\epsilon})$  for some  $\epsilon > 0$ .
- Chekuri and Korula [5]:  $O(\log^2 n)$ -approx for  $(k, 2)$ -subgraph problem with *node-connectivity constraint*.

- Here we consider the instances in which the underlying graph  $G$  is metric:

**Theorem:** For the  $(k, \lambda)$ -subgraph problem on metric graphs, there is an  $O(1)$ -approximation algorithm.

- Here we consider the instances in which the underlying graph  $G$  is metric:  
**Theorem:** For the  $(k, \lambda)$ -subgraph problem on metric graphs, there is an  $O(1)$ -approximation algorithm.
- Note that the constant factor approximation algorithms for  $k$ -MST and  $k$ -TSP are on graphs with metric cost function.

- Here we consider the instances in which the underlying graph  $G$  is metric:  
**Theorem:** For the  $(k, \lambda)$ -subgraph problem on metric graphs, there is an  $O(1)$ -approximation algorithm.
- Note that the constant factor approximation algorithms for  $k$ -MST and  $k$ -TSP are on graphs with metric cost function.
- The constant in the  $O(1)$  term is between 400-500.

- Here we consider the instances in which the underlying graph  $G$  is metric:  
**Theorem:** For the  $(k, \lambda)$ -subgraph problem on metric graphs, there is an  $O(1)$ -approximation algorithm.
- Note that the constant factor approximation algorithms for  $k$ -MST and  $k$ -TSP are on graphs with metric cost function.
- The constant in the  $O(1)$  term is between 400-500.
- Our algorithm is inspired by the work of Cheriyan and Vetta [4] for subset-node-connectivity problem.

We use two basic lower bounds on the optimum solution.

Let  $G^*$  be the optimal solution and  $\text{OPT} = c(G^*)$ ;  $T^*$  be a MST of  $G^*$ .

We use two basic lower bounds on the optimum solution.

Let  $G^*$  be the optimal solution and  $\text{OPT} = c(G^*)$ ;  $T^*$  be a MST of  $G^*$ .

### 1. Minimum Spanning Tree of $G^*$

Using the cut-constraint in the IP-formulation of MST:

$$\frac{\lambda}{2} \sum_{e \in T^*} c_e \leq \text{OPT}$$

We use two basic lower bounds on the optimum solution.

Let  $G^*$  be the optimal solution and  $\text{OPT} = c(G^*)$ ;  $T^*$  be a MST of  $G^*$ .

### 1. Minimum Spanning Tree of $G^*$

Using the cut-constraint in the IP-formulation of MST:

$$\frac{\lambda}{2} \sum_{e \in T^*} c_e \leq \text{OPT}$$

### 2. $\lambda$ nearest neighbors

if  $S_u$  is the set of  $\lambda$  nearest neighbors of  $u$  and  $s_u$  is their total distance to  $u$  then  $\frac{1}{2} \sum_{u \in T^*} s_u \leq \text{OPT}$

We use two basic lower bounds on the optimum solution.

Let  $G^*$  be the optimal solution and  $\text{OPT} = c(G^*)$ ;  $T^*$  be a MST of  $G^*$ .

### 1. Minimum Spanning Tree of $G^*$

Using the cut-constraint in the IP-formulation of MST:

$$\frac{\lambda}{2} \sum_{e \in T^*} c_e \leq \text{OPT}$$

### 2. $\lambda$ nearest neighbors

if  $S_u$  is the set of  $\lambda$  nearest neighbors of  $u$  and  $s_u$  is their total distance to  $u$  then  $\frac{1}{2} \sum_{u \in T^*} s_u \leq \text{OPT}$

Our algorithm presents a solution whose cost is bounded within an  $O(1)$ -factor of these two bounds.

The algorithm has two main phases.

The algorithm has two main phases.

- In Phase 1, we obtain a  $(k - \lambda/7, \lambda)$ -subgraph, call it  $H$ , which has cost  $O(\text{OPT})$ .

The algorithm has two main phases.

- In Phase 1, we obtain a  $(k - \lambda/7, \lambda)$ -subgraph, call it  $H$ , which has cost  $O(\text{OPT})$ .
- In Phase 2, we show how to expand  $H$  to a  $(k, \lambda)$ -subgraph, while keeping the cost within  $O(\text{OPT})$ .

## Algorithm for Phase 1

To find a low cost  $(k - O(\lambda), \lambda)$ -subgraph:

- Create a new graph  $G'(V \cup V', E')$  from  $G$  by creating a new vertex  $u'$  for each  $u \in G$  and  $E' = E \cup \{uu' | u \in V\}$ ,  $c(uu') = s_u$ .

## Algorithm for Phase 1

To find a low cost  $(k - O(\lambda), \lambda)$ -subgraph:

- Create a new graph  $G'(V \cup V', E')$  from  $G$  by creating a new vertex  $u'$  for each  $u \in G$  and  $E' = E \cup \{uu' | u \in V\}$ ,  $c(uu') = s_u$ .
- For every other edge in  $G'$  multiply its weight by  $\lambda$ .

## Algorithm for Phase 1

To find a low cost  $(k - O(\lambda), \lambda)$ -subgraph:

- Create a new graph  $G'(V \cup V', E')$  from  $G$  by creating a new vertex  $u'$  for each  $u \in G$  and  $E' = E \cup \{uu' | u \in V\}$ ,  $c(uu') = s_u$ .
- For every other edge in  $G'$  multiply its weight by  $\lambda$ .
- Using a  $\rho$ -approx alg, say ST-alg, for  $k$ -Steiner tree, find a  $k$ -Steiner tree  $T'$  in  $G'$  on terminal set  $V'$ .

## Algorithm for Phase 1

To find a low cost  $(k - O(\lambda), \lambda)$ -subgraph:

- Create a new graph  $G'(V \cup V', E')$  from  $G$  by creating a new vertex  $u'$  for each  $u \in G$  and  $E' = E \cup \{uu' | u \in V\}$ ,  $c(uu') = s_u$ .
- For every other edge in  $G'$  multiply its weight by  $\lambda$ .
- Using a  $\rho$ -approx alg, say ST-alg, for  $k$ -Steiner tree, find a  $k$ -Steiner tree  $T'$  in  $G'$  on terminal set  $V'$ .
- Note that  $T'$  minimizes (approximately)  

$$\sum_{u \in T'} s_u + \lambda \sum_{e \in T'} c_e$$
 and has at least  $k$  nodes of  $G$ .

## Algorithm for Phase 1

- Using the two lower bounds mentioned, it is easy to show that:

**Claim:**  $c(T') = 4\rho\text{OPT}$ .

Let  $T_0 \subseteq G$  be the tree obtained by deleting dummy vertices of  $T'$ .

## Algorithm for Phase 1

- Using the two lower bounds mentioned, it is easy to show that:

**Claim:**  $c(T') = 4\rho\text{OPT}$ .

Let  $T_0 \subseteq G$  be the tree obtained by deleting dummy vertices of  $T'$ .

- We'll pick some vertices  $v \in T_0$  such that  $|\bigcup_v S_v| \approx k$ . Make a clique of each such vertex  $v$  together with its neighbors in  $S_v$ .

## Algorithm for Phase 1

- Using the two lower bounds mentioned, it is easy to show that:

**Claim:**  $c(T') = 4\rho\text{OPT}$ .

Let  $T_0 \subseteq G$  be the tree obtained by deleting dummy vertices of  $T'$ .

- We'll pick some vertices  $v \in T_0$  such that  $|\bigcup_v S_v| \approx k$ .  
Make a clique of each such vertex  $v$  together with its neighbors in  $S_v$ .
- For every  $(u, v) \in T_0$  put a matching between the vertices in  $S_u - S_v$  and  $S_v - S_u$  to obtain  $\lambda$ -edge-connectivity.

## Algorithm for Phase 1

More details on how to do it...

- Let  $v_1, \dots, v_k$  be an ordering of vertices of  $T_0$  s.t.  
 $s_{v_1} \leq s_{v_2} \leq \dots s_{v_k}$ .

## Algorithm for Phase 1

More details on how to do it...

- Let  $v_1, \dots, v_k$  be an ordering of vertices of  $T_0$  s.t.  
 $s_{v_1} \leq s_{v_2} \leq \dots s_{v_k}$ .
- We call the set  $S_{v_i}$  the **ball** with center  $v_i$  and  $B_{v_i} \subseteq S_{v_i}$ , called the **core**, is the set of nodes with distance at most  $2s_{v_i}/\lambda$  to  $v_i$ .

## Algorithm for Phase 1

More details on how to do it...

- Let  $v_1, \dots, v_k$  be an ordering of vertices of  $T_0$  s.t.  
 $s_{v_1} \leq s_{v_2} \leq \dots s_{v_k}$ .
- We call the set  $S_{v_i}$  the **ball** with center  $v_i$  and  $B_{v_i} \subseteq S_{v_i}$ , called the **core**, is the set of nodes with distance at most  $2s_{v_i}/\lambda$  to  $v_i$ .
- We use a clustering to obtain a set of Active/Inactive balls:
  - **Active vs. Inactive Balls**: Every vertex is active unless it is **close** to an active ball with smaller  $s_u$  value.
  - The cores of active balls are disjoint.

## Algorithm for Phase 1

More details on how to do it...

- Let  $v_1, \dots, v_k$  be an ordering of vertices of  $T_0$  s.t.  
 $s_{v_1} \leq s_{v_2} \leq \dots s_{v_k}$ .
- We call the set  $S_{v_i}$  the **ball** with center  $v_i$  and  $B_{v_i} \subseteq S_{v_i}$ , called the **core**, is the set of nodes with distance at most  $2s_{v_i}/\lambda$  to  $v_i$ .
- We use a clustering to obtain a set of Active/Inactive balls:
  - **Active vs. Inactive Balls**: Every vertex is active unless it is **close** to an active ball with smaller  $s_u$  value.
  - The cores of active balls are disjoint.
- Let  $i^*$  be the smallest index such that  $U_{i^*} = \bigcup_{\text{active } v_j, j \leq i^*} S_{v_j}$  has at least  $k - \lambda/7$  nodes. We discard vertices  $v_j$  with  $j > i^*$ .

## Algorithm for Phase 1

More details on how to do it...

- Let  $v_1, \dots, v_k$  be an ordering of vertices of  $T_0$  s.t.  
 $s_{v_1} \leq s_{v_2} \leq \dots s_{v_k}$ .
- We call the set  $S_{v_i}$  the **ball** with center  $v_i$  and  $B_{v_i} \subseteq S_{v_i}$ , called the **core**, is the set of nodes with distance at most  $2s_{v_i}/\lambda$  to  $v_i$ .
- We use a clustering to obtain a set of Active/Inactive balls:
  - Active vs. Inactive Balls:** Every vertex is active unless it is **close** to an active ball with smaller  $s_u$  value.
  - The cores of active balls are disjoint.
- Let  $i^*$  be the smallest index such that  $U_{i^*} = \bigcup_{\text{active } v_j, j \leq i^*} S_{v_j}$  has at least  $k - \lambda/7$  nodes. We discard vertices  $v_j$  with  $j > i^*$ . Note that  $k - \frac{\lambda}{7} \leq |U_{i^*}| \leq k + \frac{6\lambda}{7}$ .

## Algorithm for Phase 1

- 1 By short-cutting over non-active nodes in  $T_0$ , we obtain tree  $T_1$ . Then for each active nodes  $v_j \in U_{i*}$  make a clique on  $S_{v_j}$ .

## Algorithm for Phase 1

- ① By short-cutting over non-active nodes in  $T_0$ , we obtain tree  $T_1$ . Then for each active nodes  $v_j \in U_{i^*}$  make a clique on  $S_{v_j}$ .
- ② For every  $(u, v) \in T_1$  put a matching between the vertices in  $S_u - S_v$  and  $S_v - S_u$  to obtain  $\lambda$ -edge-connectivity.

## Algorithm for Phase 1

- ① By short-cutting over non-active nodes in  $T_0$ , we obtain tree  $T_1$ . Then for each active nodes  $v_j \in U_{i*}$  make a clique on  $S_{v_j}$ .
- ② For every  $(u, v) \in T_1$  put a matching between the vertices in  $S_u - S_v$  and  $S_v - S_u$  to obtain  $\lambda$ -edge-connectivity.
- ③ It can be shown that the resulting graph  $H$  is  $\lambda$ -edge-connected, has at least  $k - \lambda/7$  nodes and has cost at most  $28\rho\text{OPT}$ .

Two ways to augment  $H$  to size  $k$  in Phase 2

## Phase 2:

How to expand  $H$  to have size  $k$ .

$\forall u \in G \setminus H$ : let  $d(u, H)$  be the distance between  $u$  and  $H$ .

Two ways to augment  $H$  to size  $k$  in Phase 2

## Phase 2:

How to expand  $H$  to have size  $k$ .

$\forall u \in G \setminus H$ : let  $d(u, H)$  be the distance between  $u$  and  $H$ .

### Case 1

If there is a set  $A \subseteq G \setminus H$  of  $k - |H|$  vertices s.t. has a **low-cost matching** between  $A$  and  $H$  then we can augment  $H$  with small cost.

Two ways to augment  $H$  to size  $k$  in Phase 2

## Phase 2:

How to expand  $H$  to have size  $k$ .

$\forall u \in G \setminus H$ : let  $d(u, H)$  be the distance between  $u$  and  $H$ .

### Case 1

If there is a set  $A \subseteq G \setminus H$  of  $k - |H|$  vertices s.t. has a **low-cost matching** between  $A$  and  $H$  then we can augment  $H$  with small cost.

- connect each  $u_i$  to  $S_{M(u_i)}$  to obtain  $\lambda$ -edge-connectivity.

Total cost added:

$$\lambda c(M) + 2c(H)$$

- Show if  $|G^* \setminus H| \leq \lambda/3$ , then this can be done with

$$c(M) \leq \frac{6\text{OPT}}{\lambda}$$

Two ways to augment  $H$  to size  $k$  in Phase 2

## Case 2

If there is a vertex  $u \in G \setminus H$  s.t.  $s_u + d(u, H)$  is small and  $S_u$  contains at least  $\lambda/7$  vertices in  $G \setminus H$  then we can augment  $H$  with small cost.

- It can be shown that if  $|G^* \setminus H| > \lambda/3$ , i.e. Case 1 does not happen, then this happens
- The cost of augmenting  $H$  in this case is  $\leq 12\text{OPT} + 3c(H)$ .

# Conclusion

- So we can extend  $H$  to a  $(k, \lambda)$ -subgraph by spending a total of at most  $12\text{OPT} + 3c(H)$ .
- Recalling that  $c(H) = O(\text{OPT})$ , the total approximation ratio is  $18 + 108\rho$  with  $\rho \leq 4$  being the ratio for  $k$ -Steiner tree.
- Getting a small constant factor approximation seems challenging, for general values of  $\lambda$ .
- For general cost functions, even for the special case of  $\lambda = 3$ , there is no known non-trivial approximation algorithm or lower bound.
